# CSG1105 Workshop Two

---

## 1 INTRODUCTION

This week will be a short lab to build some basic skills and understanding regarding IP addresses and Protocol layering.

## 2 IP ADDRESSES

An **IP Address** is required for any two devices on an IP-based network to communicate.

### 2.1 Finding your IP address

Most computer users are unaware of the underlying mechanisms used for establishing an Internet client/server connection. Most modern devices have an operating system that hides the complexity via additional software that attempts to automatically link the device to a Wi-Fi router/modem connected to the Internet Service Provider (ISP) via copper, fibre optic or cellular connections.

#### 2.1.1 Windows

1. Open a command prompt (WinKey+R, "cmd")
2. Type `ipconfig` and Enter

```
Wireless LAN adapter WiFi:
```

```
Connection-specific DNS Suffix . : modem
IPv6 Address. . . . . : 2001:8004:1df1:9238:ec12:cd1e:54e:b01e
Temporary IPv6 Address. . . . . : 2001:8004:1df1:9238:7806:8bac:5606:add4
Link-local IPv6 Address . . . . . : fe80::ec12:cd1e:54e:b01e%12
IPv4 Address. . . . . : 192.168.0.100
Subnet Mask . . . . . : 255.255.255.0
Default Gateway . . . . . : fe80::a691:blff:fe71:659f%12
192.168.0.1
```

### 2.1.2 OS X

1. Use Finder to launch Applications->Utilities->Terminal
2. Type `ifconfig` and Enter

```
en1:  flags=8863<UP,BROADCAST,SMART,RUNNING,SIMPLEX,MULTICAST> mtu 1500
options=400<CHANNEL_IO>
ether  1c:36:bb:ef:cf:3a
inet6  fe80::495:223c:a5eb:6f39%en1 prefixlen 64 secured scopeid 0x5
inet  10.1.1.8 netmask 0xffffffff00 broadcast 10.1.1.255
nd6    options=201<PERFORMNUD,DAD>
media:  autoselect
status:  active.
```

### 2.1.3 Private and Public IP

For both Windows and OS X, the interface name will be dependant upon your system configuration and also if you're using a cabled or wired connection. If working from home, the IP may begin with either **192.168** or **10.0**. These both belong to **private** IP ranges. They will be mapped to a public IP using a protocol called **NAT** (More on this later). To find your public IP, use a browser to open **google.com** and search for "what is my IP". My public IP is 58.169.xxx.yyy (**don't reveal your public IP!**). Whatever is returned will have been allocated to you by your ISP automatically and may change from time to time. Later we will be looking at the mechanism for how IPs are allocated, both private and public.

### 2.1.4 Network Masks

The Windows example shows a dotted-decimal subnet mask of 255.255.255.0.

In binary, this is 11111111.11111111.11111111.00000000.

Applying the subnet mask to the IP will reveal a network of **192.168.0.0**.

The OS X example shows a subnet mask (or netmask) as a hexadecimal number 0xffffffff00.

In binary, this is also 11111111.11111111.11111111.00000000 (check this for yourself).

Applying the subnet mask to the IP will reveal a network of **10.1.1.0**.

In other words, both these networks have 24 bits of network address and 8 bits of host address.

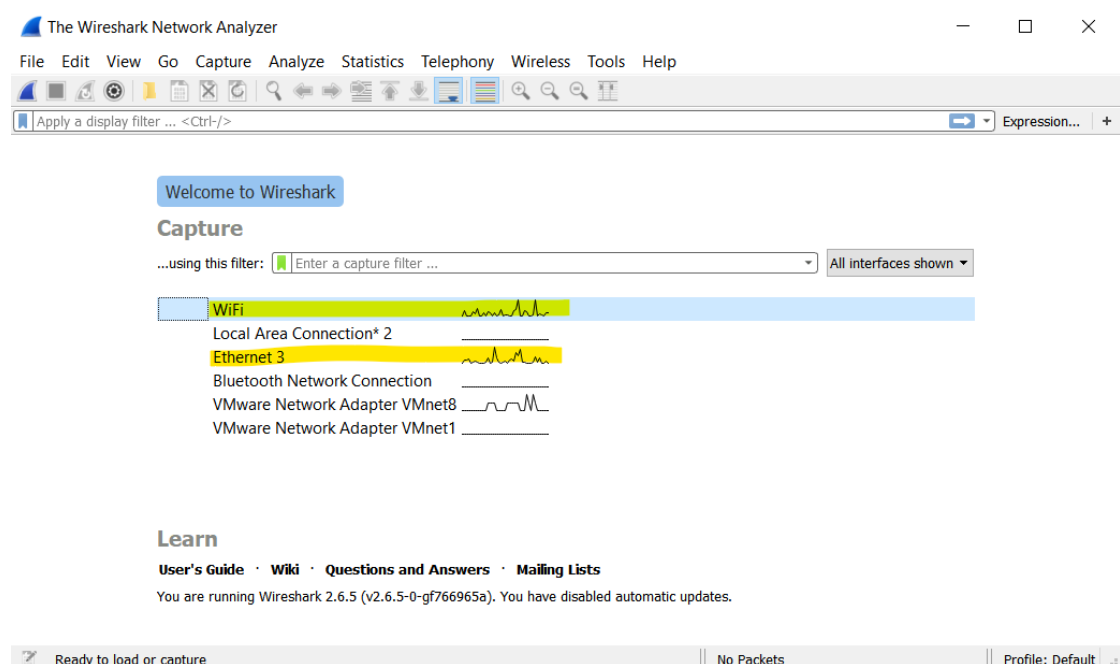

## 3 USING WIRESHARK

### 3.1 What is Wireshark?

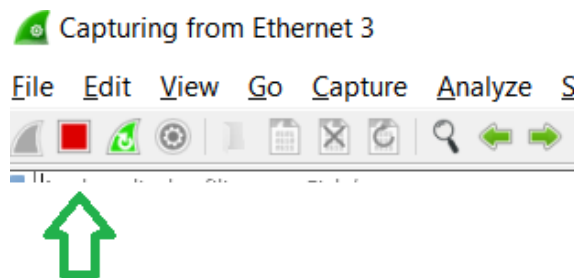

**Wireshark** is a network packet analyser. It allows us to capture traffic on a network interface and save it to a file for latter analysis. Wirehark is available at no cost for Windows, OS X and Linux. It may be downloaded from <https://www.wireshark.org/>. (If you are running this on your own machine, please download and install Wireshark at this point. Follow the instructions for your OS/platform.) In today's exercise, we are going to use it to examine protocol stacking.

#### 3.1.1 Run Wireshark

Use the appropriate OS menu to locate and launch Wireshark

1. In the above screen capture, I have highlighted the two available network interfaces, WiFi and Wired (Ethernet 3). Again, this will vary, depending upon the PC you are working on. You can see the activity graph, indicating traffic on the specific interface. Double-clicking on an interface begins capturing traffic from that interface.
2. Double click on the interface that connects your PC to the Internet.
3. Quickly open a browser to <http://www.bom.gov.au>
4. Wait for a minute, then stop the capture by clicking the stop icon.

5. . You'll notice there is three main sections to the captured data.
  - a) The list of all captured packets; this contains information such as source and destination address, protocol, length and info.
  - b) A layered view of the selected packet we are viewing, with more information provided to us
  - c) The view of the frames in hexadecimal and ASCII

The image shows a Wireshark packet capture window titled '\*Ethernet 3'. The menu bar includes File, Edit, View, Go, Capture, Analyze, Statistics, Telephony, Wireless, Tools, and Help. The toolbar contains various icons for packet capture and analysis. The packet list pane shows a table of captured packets with columns for No., Time, Source, Destination, Protocol, Length, and Info. The packet details pane shows the structure of the selected packet (No. 1), including Ethernet II, Internet Protocol Version 4, User Datagram Protocol, and Domain Name System (response). The packet bytes pane shows the raw data of the selected packet in hexadecimal and ASCII.

| No. | Time     | Source                 | Destination            | Protocol | Length | Info                          |

wireshark\_C356E69D-E8CE-4B80-9227-8279D99D31DC\_20200229070409\_a00248.pcapng | Packets: 283 · Displayed: 283 (100.0%) | Profile: Default

We can order our list of captured packets by any of the columns, so if we wanted to view the largest traffic, we can sort by Length or how many ARP or TCP requests are being made we could sort by Protocol, for now though, leave it sorted by the packet number.

- Above our list of captured packets, you'll notice a **Apply a display filter:** field. In this field we want to track the information we just generated by our telnet request. So, let's filter only HTTP protocol packets by typing in HTTP and then clicking on **apply** (the white arrow on a grey background) to the right. Below is an example of our new view:

- If we start selecting these packets we can see the information in our layer viewer has the same structure for every HTTP packet, but the information contained within changes. Without clicking on the '>' next to each one we can select the layer and find the part of the frame in the frame viewer below that it responds to. If we select the first one starting with 'Frame' you'll see the entire frame below is highlighted, moving down, when we select 'Ethernet II' we can see what part of the frame the Ethernet information is (MAC addresses etc.). Selecting 'Internet Protocol Version 4' shows the source and destination addresses part of the frame; selecting 'Transmission Control Protocol' shows the where in the frame the ports and sequence information is stored. Finally, selecting 'HTTP' shows us the section of the frame specifying that it is HTTP and the data being transferred. Clicking on the '>' next to each layer allows us to see the individual information provided in each layer, clicking on that newly revealed information shows where in the frame it is stored.
- In the following steps, refer back to the lecture notes regarding the TCP/IP network model layers and PDU names for each layer.
- Clicking on the '>' next to **Transmission Control Protocol** displays the contents of the TCP header. In this header, information on the TCP **segment** may be seen. In the screen capture, the source port (52015) and destination port (80, standard for a HTTP server) are followed by additional fields including the segment length and sequence numbers.

```

```

12. Got to the menu at the top of the Wireshark screen and select the **Analyze** option. Scroll down to the **Follow** option and select **HTTP Stream**. This will open a new window displaying the HTTP requests in **Red** and the HTTP Server responses in **Blue**. Scroll through the window and try to relate some of the content to what was displayed in the browser.

The image shows a Wireshark window titled "Wireshark · Follow HTTP Stream (tcp.stream eq 13) · Ethernet 3". The window displays the details of an HTTP stream. The request is shown in red text, and the response is shown in blue text. The request is a GET request for the root of the website. The response is an HTTP 200 OK status with various headers including Content-Encoding: gzip, Content-Type: text/html; charset=UTF-8, and Server: Apache. The body of the response shows the beginning of an HTML document with a doctype declaration and some meta tags.

```
GET / HTTP/1.1

13. The server at <http://www.bom.gov.au> is not using encryption, so the contents of the frames may be viewed as we have seen. Start a new Wireshark capture (by clicking on the shark fin icon in the menu) and in your browser, open <https://www.ecu.edu.au>, then stop the capture.
14. In the capture, apply a filter for TCP and find a frame that contains your IP as the origin. You will notice that the destination port is now **443**, indicating that we are communicating with an encrypted HTTP server.

| No. | Time      | Source       | Destination  | Protocol | Length | Info                          |

> Frame 1: 93 bytes on wire (744 bits), 93 bytes captured (744 bits) on interface 0  
 > Ethernet II, Src: 34:48:ed:a3:22:ba (34:48:ed:a3:22:ba), Dst: Sagemcom\_82:cc:e9 (24:7f:20:82:cc:e9)  
 > Internet Protocol Version 4, Src: 10.0.0.8, Dst: 172.217.25.132  
 > Transmission Control Protocol, Src Port: 65490, Dst Port: 443, Seq: 1, Ack: 1, Len: 39  
 Source Port: 65490  
 Destination Port: 443  
 [Stream index: 0]  
 [TCP Segment Len: 39]  
 Sequence number: 1 (relative sequence number)

15. Use **Analyse->Follow->TCP Stream**. The resulting capture will be encrypted and you should not be able to decipher anything.

16. Start a new Wireshark capture and let it run for a few minutes as you browse the web. Stop the capture and explore the content captured, noting the types of traffic in the **protocol** column. There are many to be seen, some of which we have discussed (DNS, TCP, HTTP) some of which will be covered in future weeks (ARP, DHCP, ICMP, TLS) and some which are out of scope for this unit.
